
tmxlib Documentation

Release 0.2.0

Petr Viktorin

January 16, 2015

1 Installation	3
2 Development	5
2.1 Tests	5
2.2 Documentation	5
3 Versioning & TODO	7
4 Contents	9
4.1 Overview	9
4.2 tmxlib Module Reference	11
5 Indices and tables	37
Python Module Index	39

tmxlib is a Python library for handling TMX tile maps. It serves a relatively specific purpose: making it easy to write scripts for automatic handling of TMX files.

If you aren't familiar with TMX, or you just want to make some maps, install [Tiled](#), a GUI editor, and play around with it. Tiled's wiki and IRC channel are places to go if you have questions about the TMX format.

If you're looking to use maps in a game, chances are *tmxlib* won't help you much. Try [pytmxloader](#), [PyTMX](#), or one of the other projects listed on the [Tiled wiki](#).

Installation

To install tmxlib, you can use `pip`: `pip install --user tmxlib`. To install system-wide, leave out the `--user` option.

If you can't find `pip` on your system, look around. In Fedora, it's named `pip-python` and lives in the `python-pip` package.

Optionally, also install the `lxml` and `Pillow` packages to speed up XML and image handling, respectively. Linux distributions are likely to have them (in Fedora, `yum install python-lxml python-imaging`). If you can't find them, use `pip` to get them.

Development

The project is hosted on [Github](#) (as `pytmxlib`), free for anyone to file bugs, clone, fork, or otherwise help make it better.

To install the library for development, navigate to the source folder, and run `python setup.py develop`.

2.1 Tests

To run tests, `pip install pytest-cov`, and run `py.test`.

Tests can be run using [tox](#), to ensure cross-Python compatibility. Make sure you have all supported Pythons (2.6, 2.7, 3.3) installed, and run `tox`.

Nowadays we use Travis CI and Coveralls to run tests after each commit:

2.2 Documentation

This documentation is generated using [Sphinx](#). To build it, `pip install sphinx` and run `make` in the `doc` directory.

Versioning & TODO

This package sports the [SemVer](#) versioning scheme. In this pre-1.0 version, that doesn't mean much.

Version 1.0 will include at least one generally useful command-line utility, most likely a crop/merge tool for maps.

Contents

4.1 Overview

Before doing anything else, import *tmxlib*.

```
>>> import tmxlib
```

4.1.1 Loading and saving

Loading a map from a file is quite easy:

```
>>> filename = 'desert.tmx'  
>>> tmxlib.Map.open(filename)  
<tmxlib.Map object at ...>
```

You can also load from a string:

```
>>> string = open('desert.tmx', 'rb').read()  
>>> map = tmxlib.Map.load(string)
```

Saving is equally easy:

```
>>> map.save('saved.tmx')  
>>> map_as_string = map.dump()
```

4.1.2 Maps

Map is tmxlib's core class.

Each map has three “size” attributes: *size*, the size of the map in tiles; *tile_size*, the pixel size of one tile; and *pixel_size*, which is the product of the two. Each of these has *height* and *width* available as separate attributes; for example *pixel_height* would give the map's height in pixels.

A map's *orientation* is its fundamental mode. Tiled currently supports ‘orthogonal’ and ‘isometric’ orientations, but tmxlib will currently not object to any other orientation (as it does not need to actually draw maps). Orthogonal orientation is the default.

Each map has a dict of properties, with which you can assign arbitrary string values to string keys.

4.1.3 Tilesets

A map has one or more tilesets, which behave as lists of tiles.

```
>>> map.tilesets
[<ImageTileset 'Desert' at ...>]
>>> tileset = map.tilesets[0]
>>> len(tileset)
48
>>> tileset[0]
<TilesetTile #0 of Desert at ...>
>>> tileset[-1]
<TilesetTile #47 of Desert at ...>
```

As a convenience, tilesets may be accessed by name instead of number. A name will always refer to the first tileset with such name.

You can also remove tilesets (using either names or indexes). However, note that to delete a tileset, the map may not contain any of its tiles.

```
>>> del map.tilesets['Desert']
Traceback (most recent call last):
...
UsedTilesetError: Cannot remove <ImageTileset 'Desert' at ...>; map contains its tiles
Traceback (most recent call last):
...
UsedTilesetError: Cannot remove <ImageTileset 'Desert' at ...>; map contains its tiles
```

(If this causes you trouble when you need to move tilesets around, use the `map.tilesets.move` method)

Tilesets are not tied to maps, which means that several maps can share the same tileset object.

In map data, tiles are referenced by the GID, which uniquely determines the tile across all the map's tilesets.

```
>>> tile = tileset[10]
>>> tile.gid(map)
11
```

Each tileset within a map has a *first gid*, the GID of its first object. The `first_gid` is always *number of tiles in all preceding tilesets + 1*. (It is written to the TMX file to help loaders, but should not be changed there.)

Modifying the list of tilesets can cause the `first_gid` to change. All affected tiles in the map will automatically be renumbered in this case.

4.1.4 Layers

As with tilesets, each map has layers. Like tilesets, these can be accessed either by index or by name.

```
>>> map.layers[0]
<TileLayer #0: 'Ground' at ...>
>>> map.layers['Ground']
<TileLayer #0: 'Ground' at ...>
```

Creating layers directly can be a hassle, so Map provides an `add_layer` method that creates a compatible empty layer.

```
>>> map.add_layer('Sky')
<TileLayer #1: 'Sky' at ...>
>>> map.add_layer('Underground', before='Ground')
<TileLayer #0: 'Underground' at ...>
```

```
>>> map.layers
[<TileLayer #0: 'Underground' at ...>, <TileLayer #1: 'Ground' at ...>, <TileLayer #2: 'Sky' at ...>]
```

Layers come in two flavors: *tile layers*, which contain a rectangular grid of tiles, and *object layers*, which contain objects. This overview will only cover the former; object layers are explained in their documentation.

4.1.5 Tile layers

A tile layer is basically a 2D array of map tiles. Index the layer with the x and y coordinates to get a MapTile object.

```
>>> layer = map.layers['Ground']
>>> layer[0, 0]
<MapTile (0, 0) on Ground, gid=30 at ...>
>>> layer[6, 7]
<MapTile (6, 7) on Ground, gid=40 at ...>
```

The MapTile object is a reference to a particular place in the map. This means that changing the MapTile object (through its *value* attribute, for example) will update the map.

The easiest way to change the map, though, is to assign a tileset tile to a location on the map.

```
>>> layer[6, 7] = map.tilesets['Desert'][29]
```

Map tiles can also be flipped around, using Tiled's three flipping flags: horizontal (H), vertical(V), and diagonal (D) flip.

```
>>> tile = layer[6, 7]
>>> tile.flipped_horizontally = True
>>> tile
<MapTile (6, 7) on Ground, gid=30 H at ...>
>>> tile.vflip()
>>> tile
<MapTile (6, 7) on Ground, gid=30 HV at ...>
>>> tile.rotate()
>>> tile
<MapTile (6, 7) on Ground, gid=30 VD at ...>
```

Map tiles are true in a boolean context iff they're not empty (i.e. their *gid* is not 0).

4.1.6 Images and pixels

The library has some basic support for working with tile images.

If tmxlib can't find `Pillow` (or `PIL`), it will use the pure-python `png` package. This is very slow when reading the pictures, and it can only handle PNG files. For this reason, it's recommended that you install PIL to work with images.

```
>>> map.tilesets['Desert'][0].get_pixel(0, 0)
(1.0, 0.8156862..., 0.5803921..., 1.0)
>>> map.layers['Ground'][0, 0].get_pixel(0, 0)
(1.0, 0.8156862..., 0.5803921..., 1.0)
```

4.2 tmxlib Module Reference

The main module exports the most important classes directly:

- [Map](#), the main object
- Layer objects: [ImageLayer](#), [ObjectLayer](#), and [TileLayer](#)
- [MapTile](#)
- [ImageTileset](#), the only kind of tileset so far, and [TilesetTile](#)
- Map object classes: [PolygonObject](#), [PolylineObject](#), [RectangleObject](#), and [EllipseObject](#)
- Exceptions, [UsedTilesetError](#) and [TilesetNotInMapError](#)

See submodule documentation for more details:

4.2.1 The `tmxlib.map` module

Map

```
class tmxlib.map.Map(size,      tile_size,      orientation='orthogonal',      background_color=None,
                      base_path=None, render_order=None)
```

A tile map, tmxlib's core class

init arguments, which become attributes:

size

a (height, width) pair specifying the size of the map, in tiles

tile_size

a pair specifying the size of one tile, in pixels

orientation

The orientation of the map ('orthogonal', 'isometric', or 'staggered')

background_color

The background color for the map, as a triple of floats (0..1)

Other attributes:

tilesets

A TilesetList of tilesets this map uses

layers

A LayerList of layers this map uses

properties

A dict of properties, with string (or unicode) keys & values

pixel_size

The size of the map, in pixels. Not settable directly: use `size` and `tile_size` for that.

end_gid

The first GID that is not available for tiles. This is the `end_gid` for the map's last tileset.

Unpacked size attributes:

Each “size” property has corresponding “width” and “height” properties.

height

width

tile_height

tile_width

```
pixel_height  
pixel_width
```

Methods:

```
add_layer (name, before=None, after=None, layer_class=None)
```

Add an empty layer with the given name to the map.

By default, the new layer is added at the end of the layer list. A different position may be specified with either of the *before* or *after* arguments, which may be integer indices or names.

layer_class defaults to TileLayer

```
add_tile_layer (name, before=None, after=None)
```

Add an empty tile layer with the given name to the map.

See add_layer

```
add_object_layer (name, before=None, after=None)
```

Add an empty object layer with the given name to the map.

See add_layer

```
add_image_layer (name, image, before=None, after=None)
```

Add an image layer with the given name and image to the map.

See add_layer

```
all_tiles ()
```

Yield all tiles in the map, including tile objects

```
all_objects ()
```

Yield all objects in the map

```
get_tiles (x, y)
```

For each tile layer, yield the tile at the given position.

```
check_consistency ()
```

Check that this map is okay.

Most checks are done when reading a map, but if more are required, call this method after reading. This will do a more expensive check than what's practical from within readers.

Loading and saving (see `tmxlib.fileio.ReadWriteBase` for more information):

```
classmethod open (filename, shared=False)
```

```
classmethod load (string)
```

```
save (filename)
```

```
dump (string)
```

```
to_dict ()
```

Export to a dict compatible with Tiled's JSON plugin

You can use e.g. a JSON or YAML library to write such a dict to a file.

```
classmethod from_dict (dct, *args, **kwargs)
```

Import from a dict compatible with Tiled's JSON plugin

Use e.g. a JSON or YAML library to read such a dict from a file.

Parameters

- **dct** – Dictionary with data
- **base_path** – Base path of the file, for loading linked resources

4.2.2 The tmxlib.layer module

Layer

```
class tmxlib.layer.Layer (map, name, visible=True, opacity=1)
```

Base class for map layers

init arguments, which become attributes:

map

The map this layer belongs to. Unlike tilesets, layers are tied to a particular map and cannot be shared.

name

Name of the layer

visible

A boolean setting whether the layer is visible at all. (Actual visibility also depends on *opacity*)

opacity

Floating-point value for the visibility of the layer. (Actual visibility also depends on *visible*)

Other attributes:

properties

Dict of properties with string (or unicode) keys and values.

type

'tiles' if this is a tile layer, 'objects' if it's an object layer, 'image' for an object layer.

index

Index of this layer in the layer list

A Layer is false in a boolean context iff it is empty, that is, if all tiles of a tile layer are false, or if an object layer contains no objects.

Methods:

all_objects()

Yield all objects in this layer

all_tiles()

Yield all tiles in this layer, including empty ones and tile objects

Dict import/export:

to_dict()

Export to a dict compatible with Tiled's JSON plugin

classmethod from_dict (dct, *args, **kwargs)

Import from a dict compatible with Tiled's JSON plugin

TileLayer

```
class tmxlib.layer.TileLayer (map, name, visible=True, opacity=1, data=None)
```

A tile layer

Acts as a 2D array of MapTile's, indexed by [x, y] coordinates. Assignment is possible either via numeric values, or by assigning a TilesetTile. In the latter case, if the tileset is not on the map yet, it is added.

See [Layer](#) documentation for most init arguments.

Other init arguments, which become attributes:

data

Optional list (or array) containing the values of tiles in the layer, as one long list in row-major order. See `TileLikeObject.value` for what the numbers will mean.

Methods:

all_objects()

Yield all objects in this layer

all_tiles()

Yield all tiles in this layer, including empty ones.

Tile access:

__getitem__(pos)

Get a `MapTile` representing the tile at the given position.

Supports negative indices by wrapping in the obvious way.

__setitem__(pos, value)

Set the tile at the given position

The set value can be either a raw integer value, or a `TilesetTile`. In the latter case, any tileset not in the map yet will be added to it.

Supports negative indices by wrapping in the obvious way.

Methods to be overridden in subclasses:

value_at(pos)

Return the value at the given position

See `MapTile` for an explanation of the value.

set_value_at(pos, new)

Sets the raw value at the given position

See `MapTile` for an explanation of the value.

Dict import/export:

to_dict()

Export to a dict compatible with Tiled's JSON plugin

classmethod from_dict(dct, *args, **kwargs)

Import from a dict compatible with Tiled's JSON plugin

ObjectLayer

class tmxlib.layer.ObjectLayer(map, name, visible=True, opacity=1, color=None)

A layer of objects.

Acts as a `named list` of objects. This means semantics similar to layer/tiles lists: indexing by name is possible, where a name references the first object of such name.

See `Layer` for inherited init arguments.

ObjectLayer-specific init arguments, which become attributes:

color

The intended color of objects in this layer, as a triple of floats (0..1)

Methods:

all_objects()
Yield all objects in this layer (i.e. return self)

all_tiles()
Yield all tile objects in this layer, in order.

Dict import/export:

to_dict()
Export to a dict compatible with Tiled's JSON plugin

classmethod from_dict(dct, *args, **kwargs)
Import from a dict compatible with Tiled's JSON plugin

ImageLayer

class tmxlib.layer.ImageLayer(map, name, visible=True, opacity=1, image=None)
An image layer

See [Layer](#) documentation for most init arguments.

Other init arguments, which become attributes:

image
The image to use for the layer

Dict import/export:

to_dict()
Export to a dict compatible with Tiled's JSON plugin

classmethod from_dict(dct, *args, **kwargs)
Import from a dict compatible with Tiled's JSON plugin

LayerList

class tmxlib.layer.LayerList(map, lst=None)
A list of layers.

Allows indexing by name, and can only contain layers of a single map.

See [NamedElementList](#) for LayerList's methods.

4.2.3 The tmxlib.tile module

TileLikeObject

class tmxlib.tile.TileLikeObject
Bases: [tmxlib.helpers.TileMixin](#)

Base tile-like object: regular tile or tile object.

Has an associated layer and value, and can be flipped, etc.

A TileLikeObject is “true” iff there’s a tile associated with it. Empty, “false” tiles have a GID of zero.

Note: Subclasses should use the `_value` attribute for your own purposes. The `value` allows setting itself to

TilesetTiles, has checks, etc.

Tile attributes & methods:

tileset

Get the referenced tileset

value

Numeric value of a tile, representing the image and transformations.

See the TMX format for a hopefully more detailed specification. The upper bits of this number are used for flags:

- 0x80000000: tile is flipped horizontally.
- 0x40000000: tile is flipped vertically.
- 0x20000000: tile is flipped diagonally (axes are swapped).
- 0x10000000: tmxlib reserves this bit for now, just because 0xFFFFFFFF is a nice round number.

The rest of the value is zero if the layer is empty at the corresponding spot (or an object has no associated tile image), or it holds the GID of the tileset-tile.

The GID can be computed as $1 + X + Y$ where X is the number of tiles in all tilesets preceding the tile's, and Y is the number of the tile within its tileset.

The individual parts of value are reflected in individual properties:

- flipped_horizontally (0x80000000)
- flipped_vertically (0x40000000)
- flipped_diagonally (0x20000000)
- gid (0x0FFFFFFF)

The properties themselves have a *value* attribute, e.g. `tmxlib.MapTile.flipped_diagonally.value == 0x20000000`.

gid

flipped_horizontally

flipped_vertically

flipped_diagonally

See [value](#)

tileset_tile

Get the referenced tileset tile

number

Get the number of the referenced tileset tile

image

Get the image of the tile. (N.B. see full docstring!)

N.B. No transformations are applied to the image. This can change in future versions. Use `self.tileset_tile.image` for future-safe behavior.

get_pixel(x, y)

Get the pixel at the given x, y coordinates.

Handles negative indices in the obvious way.

tile_to_image_coordinates(x, y)

Transform map-tile pixel coordinates to tileset-tile pixel coords.

Handles negative indices in the obvious way.

Flipping helpers:

hflip()
Flip the tile horizontally

vflip()
Flip the tile vertically

rotate(*degrees*=90)
Rotate the tile clockwise by the specified number of degrees

Note that tiles can only be rotated in 90-degree increments.

Inherited:

map

size

Size of the referenced tile, taking rotation into account. The size is given in map tiles, i.e. “normal” tiles are 1x1. A “large tree” tile, twice as big as a regular tile, would have a size of (1, 2). The size will be given as floats.

Empty tiles have (0, 0) size.

MapTile

class tmxlib.tile.MapTile(*layer, pos*)
References a particular spot on a tile layer

MapTile object can be hashed and they compare equal if they refer to the same tile of the same layer.

init arguments, which become attributes:

layer

The associated layer.

pos

The associated coordinates, as (x, y), in tile coordinates.

See [TileLikeObject](#) for attributes and methods shared with tile objects.

properties

Properties of the *referenced* tileset-tile

Note: Changing this will change properties of all tiles using this image. Possibly even across more maps if tilesets are shared.

See [TilesheetTile](#).

4.2.4 The tmxlib.tileset module

Tilesheet

class tmxlib.tileset.Tilesheet(*name, tile_size*)
Base class for a tilesheet: bank of tiles a map can use.

There are two kinds of tilesheets: external and internal. Internal tilesheets are specific to a map, and their contents are saved inside the map file. External tilesheets are saved to their own file, so they may be shared between several maps. (Of course, any tilesheet can be shared between maps at the Python level; this distinction only applies to what happens on disk.) External tilesheets have the file path in their *source* attribute; internal ones have *source* set to None.

tmxlib will try to ensure that each external tileset gets only loaded once, as the resulting Python objects are shared. See `ReadWriteBase.open()` for more information.

init arguments, which become attributes:

name

Name of the tileset

tile_size:

A (width, height) pair giving the size of a tile in this tileset. In cases where a tileset can have unequally sized tiles, the tile size is not defined. This means that this property should not be used unless working with a specific subclass that defines tile_size better.

source

For external tilesets, the file name for this tileset. None for internal ones.

Other attributes:

properties

A dict with string (or unicode) keys and values. Note that the official TMX format does not support tileset properties (yet), so editors like Tiled will remove these. (tmxlib saves and loads them just fine, however.)

terrains

A `TerrainList` of terrains belonging to this tileset. Note that tileset tiles reference these by index, and the indices are currently not updated when the TerrainList is modified. This may change in the future.

tile_offset

An offset in pixels to be applied when drawing a tile from this tileset.

Unpacked versions of tuple attributes:

tile_width**tile_height****tile_offset_x****tile_offset_y**

Loading and saving (see `tmxlib.fileio.ReadWriteBase` for more information):

classmethod open (filename, shared=False)**classmethod load (string)****save (filename)****dump (string)****to_dict (**kwargs)**

Export to a dict compatible with Tiled's JSON plugin

classmethod from_dict (dct, base_path=None)

Import from a dict compatible with Tiled's JSON plugin

List-like access:

__getitem__ (n)

Get tileset tile with the given number.

Supports negative indices by wrapping around, as one would expect.

`__len__()`

Return the number of tiles in this tileset.

Subclasses need to override this method.

`__iter__()`

Iterate through tiles in this tileset.

Overridable methods:

`tile_image(number)`

Return the image used by the given tile.

Usually this will be a region of a larger image.

Subclasses need to override this method.

GID calculation methods:

Note: `TilesetList` depends on the specific GID calculation algorithm provided by these methods to renumber a map's tiles when tilesets are moved around. Don't override these unless your subclass is not used with vanilla TilesetLists.

`first_gid(map)`

Return the first gid used by this tileset in the given map

`end_gid(map)`

Return the first gid after this tileset in the given map

ImageTileset

```
class tmxlib.tileset.ImageTileset(name, tile_size, image, margin=0, spacing=0, source=None,  
                                base_path=None)
```

A tileset whose tiles form a rectangular grid on a single image.

This is the default tileset type in Tiled.

init arguments, which become attributes:

`name`

`tile_size`

`source`

see `Tileset`

`image`

The `Image` this tileset is based on.

`margin`

Size of a border around the image that does not contain tiles, in pixels.

`spacing`

Space between adjacent tiles, in pixels.

Other attributes:

`column_count`

Number of columns of tiles in the tileset

`row_count`

Number of rows of tiles in the tileset

See [Tilesheet](#) for generic tilesheet methods.

ImageTilesheet methods:

tile_image (*number*)

Return the image used by the given tile

TilesheetTile

class tmxlib.tilesheet.TilesheetTile (*tilesheet, number*)

Reference to a tile within a tilesheet

init arguments, which become attributes:

tilesheet

the tilesheet this tile belongs to

number

the number of the tile

Other attributes:

pixel_size

The size of the tile, in pixels. Also available as (pixel_width, pixel_height).

properties

A string-to-string dictionary holding custom properties of the tile

image

Image this tile uses. Most often this will be a region of the tilesheet's image.

terrain_indices

List of indices to the tilesheet's terrain list for individual corners of the tile. See the TMX documentation for details.

terrains

Tuple of terrains for individual corners of the tile. If no terrain is given, None is used instead.

probability

The probability that this tile will be chosen among others with the same terrain information.
May be None.

Methods:

gid (*map*)

Return the GID of this tile for a given map

The GID is a map-specific identifier unique for any tilesheet-tile the map uses.

get_pixel (*x, y*)

Get a pixel at the specified location.

Pixels are returned as RGBA 4-tuples.

TilesheetList

class tmxlib.tilesheet.TilesheetList (*map, lst=None*)

A list of tilesheets.

Allows indexing by name.

Whenever the list is changed, GIDs of tiles in the associated map are renumbered to match the new set of tilesheets.

See [NamedElementList](#) for TilesetList's methods.

modification_context (*args, **kwds)

Context manager that “wraps” modifications to the tileset list

While this manager is active, the map’s tiles are invalid and should not be touched. After all modification_contexts exit, tiles are renumbered to match the new tileset list. This means that multiple operations on the tileset list can be wrapped in a modification_context for efficiency.

If a used tileset is removed, an exception will be raised whenever the outermost modification_context exits.

4.2.5 The tmxlib.mapobject module

MapObject

class tmxlib.mapobject.**MapObject** (layer, pixel_pos, name=None, type=None)

A map object: something that’s not placed on the fixed grid

Has several subclasses.

Can be either a “tile object”, which has an associated tile much like a map-tile, or a regular (non-tile) object that has a settable size.

init arguments, which become attributes:

layer

The layer this object is on

pixel_pos

The pixel coordinates

pixel_size

Size of this object, as a (width, height) tuple, in pixels.

Only one of pixel_size and size may be specified.

size

Size of this object, as a (width, height) tuple, in units of map tiles.

name

Name of the object. A string (or unicode)

type

Type of the object. A string (or unicode). No semantics attached.

Other attributes:

objtype

Type of the object: ‘rectangle’, ‘tile’ or ‘ellipse’

properties

Dict of string (or unicode) keys & values for custom data

pos

Position of the object in tile coordinates, as a (x, y) float tuple

map

The map associated with this object

Unpacked position attributes:

x

```
y  
pixel_x  
pixel_y
```

Methods:

```
to_dict (y=None)  
    Export to a dict compatible with Tiled's JSON plugin  
classmethod from_dict (dct, layer)  
    Import from a dict compatible with Tiled's JSON plugin
```

RectangleObject

```
class tmxlib.mapobject.RectangleObject (layer, pixel_pos, size=None, pixel_size=None,  
name=None, type=None, value=0)
```

A rectangle object, either blank (sized) or a tile object

See [MapObject](#) for inherited members.

Extra init arguments, which become attributes:

pixel_size
Size of this object, as a (width, height) tuple, in pixels. Must be specified for non-tile objects, and must *not* be specified for tile objects (unless the size matches the tile).

Similar restrictions apply to setting the property (and `width` & `height`).

size
Size of this object, as a (width, height) tuple, in units of map tiles.

Shares setting restrictions with `pixel_size`. Note that the constructor will only accept one of `size` or `pixel_size`, not both at the same time.

value
Value of the tile, if it's a tile object.

See [tmxlib.tile.TileLikeObject](#) for attributes and methods shared with tiles.

EllipseObject

```
class tmxlib.mapobject.EllipseObject (layer, pixel_pos, size=None, pixel_size=None,  
name=None, type=None)
```

An ellipse object

Extra init arguments, which become attributes:

pixel_size
Size of this object, as a (width, height) tuple, in pixels. Must be specified for non-tile objects, and must *not* be specified for tile objects (unless the size matches the tile).

Similar restrictions apply to setting the property (and `width` & `height`).

size
Size of this object, as a (width, height) tuple, in units of map tiles.

Shares setting restrictions with `pixel_size`. Note that the constructor will only accept one of `size` or `pixel_size`, not both at the same time.

Unpacked size attributes:

```
width
height
pixel_width
pixel_height
```

PolygonObject

```
class tmxlib.mapobject.PolygonObject(layer, pixel_pos, size=None, pixel_size=None,
name=None, type=None, points=())
```

A polygon object

See [MapObject](#) for inherited members.

Extra init arguments, which become attributes:

points

Size of this object, as a (width, height) tuple, in pixels. Must be specified for non-tile objects, and must *not* be specified for tile objects (unless the size matches the tile).

The format is list of iterables: [(x0, y0), (x1, y1), ..., (xn, yn)]

PolylineObject

```
class tmxlib.mapobject.PolylineObject(layer, pixel_pos, size=None, pixel_size=None,
name=None, type=None, points=())
```

A polygon object

Behaves just like [PolygonObject](#), it's not closed when drawn. Has the same `points` attribute/argument as [PolygonObject](#).

4.2.6 The `tmxlib.terrain` module

Terrain

```
class tmxlib.terrain.Terrain(name, tile)
```

Represents a Tiled terrain

Init arguments, which become attributes:

name

The name of the terrain

tile

The tile that represents the terrain visually. Should be from the same tilesheet.

TerrainList

```
class tmxlib.terrain.TerrainList(lst=None)
```

append_new(name, tile)

Append a newly created Terrain to the list

4.2.7 The tmxlib.image modules

Image loading

The `open()` function provides a high-level interface to reading images.

`tmxlib.image.open(filename, trans=None, size=None)`

Open the given image file

Uses `preferred_image_class`.

Parameters

- `filename` – Name of the file to load the image from
- `trans` – Optional color that should be loaded as transparent

Note: Currently, loading images that use color-key transparency is very inefficient. If possible, use the alpha channel instead.

- `size` – Optional (width, height) tuple. If specified, the file will not be read from disk when the image size needs to be known. If and when the image is loaded, the given size is checked and an exception is raised if it does not match.

Returns

An `Image`

Note that the file is not opened until needed. This makes it possible to use maps and tilesets that refer to nonexistent images.

`tmxlib.image.preferred_image_class`

The type of the object `open()` returns depends on the installed libraries. If `Pillow` (or `PIL`) is installed, the faster `PilImage` is used; otherwise `tmxlib` falls back to `PngImage`, which works anywhere but may be lower and only supports PNG files. Both wrappers offer the same API.

`tmxlib.image.image_classes`

A list of all available image classes, listed by preference. `preferred_image_class` is the first element in this list.

Image base classes

Image Base

`class tmxlib.image_base.ImageBase`

Image base class

This defines the basic image API, shared by `Image` and `ImageRegion`.

Pixels are represented as (r, g, b, a) float tuples, with components in the range of 0 to 1.

`__getitem__(pos)`

Get a pixel or region

With a pair of integers, this returns a pixel via `get_pixel()`:

Parameters `pos` – pair of integers, (x, y)

Returns pixel at (x, y) as a (r, g, b, a) float tuple

With a pair of slices, returns a sub-image:

Parameters `pos` – pair of slices, (left:right, top:bottom)

Returns a `ImageRegion`

Image

class `tmxlib.image_base.Image` (`data=None`, `trans=None`, `size=None`, `source=None`)
An image. Conceptually, an 2D array of pixels.

Note: This is an abstract base class. Use `tmxlib.image.open()` or `tmxlib.image.preferred_image_class` to get a usable subclass.

init arguments that become attributes:

data

Data of this image, as read from disk.

size

Size of the image, in pixels.

If given in constructor, the image doesn't have to be decoded to get this information, somewhat speeding up operations that don't require pixel access.

If it's given in constructor and it does not equal the actual image size, an exception will be raised as soon as the image is decoded.

source

The file name of this image, if it is to be saved separately from maps/tilesets that use it.

trans

A color key used for transparency

Note: Currently, loading images that use color-key transparency is very inefficient. If possible, use the alpha channel instead.

Images support indexing (`img[x, y]`); see `tmxlib.image_base.ImageBase.__getitem__()`

get_pixel (`x, y`)

Get the color of the pixel at position `(x, y)` as a RGBA 4-tuple.

Supports negative indices by wrapping around in the obvious way.

Methods interesting for subclasses:

load_image ()

Load the image from `self.data`, and set `self._size`

If `self._size` is already set, assert that it equals

ImageRegion

class `tmxlib.image_base.ImageRegion` (`parent`, `top_left`, `size`)
A rectangular region of a larger image

init arguments that become attributes:

parent

The “parent” image

top_left

The coordinates of the top-left corner of the region. Will also available as `x` and `y` attributes.

size

The size of the region. Will also available as `width` and `height` attributes.

Except for the constructor and attributes, `ImageRegion` supports the same external API as `Image`:

get_pixel(*x*, *y*)

Get the color of the pixel at position (*x*, *y*) as a RGBA 4-tuple.

Supports negative indices by wrapping around in the obvious way.

4.2.8 The tmxlib.canvas and draw modules

Provides image drawing/modification capabilities

This module requires `PIL` (or `Pillow`) to be installed.

`class tmxlib.canvas.Canvas(size=(0, 0), commands=(), color=(0, 0, 0, 0))`

A mutable image

Acts as a regular `Image`, except it allows modifications.

Some operations, such as taking an `ImageRegion`, will work on an immutable copy of the canvas.

Parameters `commands` – An iterable of drawing commands to apply on the canvas right after creation

init arguments that become attributes:

size

The size of this Canvas. Will also available as `width` and `height` attributes.

color

The initial color the canvas will have

drawing methods:

`draw_image`(*image*, *pos*=(0, 0), *opacity*=1)

Paste the given image at the given position

conversion:

to_image()

Take an immutable copy of this Canvas

Returns an `Image`

internals:

pil_image

The PIL image underlying this Canvas.

Note: Modifying the returned image is not guaranteed to have an effect.

In the future there might be Canvas implementations not based on PIL; their `pil_image` attribute might only give a copy of the data. If PIL is not installed, the attribute won't be present at all.

Drawing commands

Operations on a Canvas may be specified by command objects. This allows one to flexibly filter or modify a stream of drawing operations.

```
class tmxlib.draw.DrawCommand
    A draw command

    draw(canvas)
        Apply this operation to the given Canvas

class tmxlib.draw.DrawImageCommand(image, pos=(0, 0), opacity=1)
    Command to draw an image
```

init arguments that become attributes:

```
    image
        The image to draw

    pos
        Position at which to draw the image. Will also available as x and y attributes.
```

4.2.9 The tmxlib.helpers module

Exceptions

```
exception tmxlib.helpers.UsedTilesetError
    Raised when trying to remove a tileset from a map that is uses its tiles

exception tmxlib.helpers.TilesetError
    Used when trying to use a tile from a tileset that's not in the map
```

NamedElementList

```
class tmxlib.helpers.NamedElementList(lst=None)
    A list that supports indexing by element name, as a convenience, etc

    lst[some_name] means the first element where element.name == some_name. The dict-like get
    method is provided.

    Additionally, NamedElementList subclasses can use several hooks to control how their elements are stored or
    what is allowed as elements.
```

```
    get(index_or_name, default=None)
        Same as __getitem__, but returns default if not found

    insert(index_or_name, value)
        Same as list.insert, except indices may be names instead of ints.

    insert_after(index_or_name, value)
        Insert the new value after the position specified by index_or_name
```

For numerical indexes, the same as `insert(index + 1, value)`. Useful when indexing by strings.

```
    move(index_or_name, amount)
        Move an item by the specified number of indexes

        amount can be negative. For example, "move layer down" translates to layers.move(idx, -1)

        The method will clamp out-of range amounts, so, for example, lst.move(0, -1) will do nothing.
```

Hooks for subclasses:

```
    modification_context(*args, **kwds)
        Context in which all modifications take place.
```

The default implementation nullifies the modifications if an exception is raised.

Note that the manager may nest, in which case the outermost one should be treated as an atomic operation.

retrieved_value (*item*)

Called when an item is being retrieved from the list.

Return the object that will actually be retrieved.

This method must undo any modifications that stored_value does.

stored_value (*item*)

Called when an item is being inserted into the list.

Return the object that will actually be stored.

To prevent incompatible items, subclasses may raise an exception here.

This method must undo any modifications that retrieved_value does.

Internal helpers and mixins

Dict conversion helpers

`tmxlib.helpers.from_dict_method(func)`

Decorator for from_dict classmethods

Takes a copy of the second argument (dct), and makes sure it is empty at the end.

`tmxlib.helpers.assert_item(dct, key, expected_value)`

Asserts that `dct[key] == expected_value`

Helpers for tuple properties

`tmxlib.helpers.unpacked_properties(full_prop_name, count=2)`

Return properties that “unpack” a tuple property

For example, if a class defines:

```
x, y = unpacked_properties('pos')
```

then `obj.x` will return the same as `obj.pos[0]`, and setting `obj.x` will update `obj.pos` to (new x, old y).

`class tmxlib.helpers.SizeMixin`

width

Getter/setter for `self.size[0]`

height

Getter/setter for `self.size[1]`

_wrap_coords (*x, y*)

Normalize coordinates for indexing/slicing

Positive values are unchanged, negative ones wrap around using `self.width & self.height`

Other mixins

```
class tmxlib.helpers.LayerElementMixin
    Provides a map attribute extracted from the object's layer.
```

```
class tmxlib.helpers.TileMixin
    Provides size based on pixel_size and the map

    width
        Getter/setter for self.size[0]

    height
        Getter/setter for self.size[1]

    tile_width
        Getter/setter for self.tile_size[0]

    tile_height
        Getter/setter for self.tile_size[1]

    pixel_x
        Getter/setter for self.pixel_pos[0]

    pixel_y
        Getter/setter for self.pixel_pos[1]

    x
        Getter/setter for self.pos[0]

    y
        Getter/setter for self.pos[1]
```

Helpers

```
class tmxlib.helpers.Property
    Trivial subclass of the property builtin. Allows custom attributes.
```

4.2.10 Extra members of tmxlib classes

To avoid clutter, some members aren't mentioned in their respective classes' documentation. This page documents such members, so that they can be linked.

(And also to make the doc coverage tool happy.)

```
class tmxlib.layer.TileLayer
    Layer methods

        TileLayer.to_dict()
            Export to a dict compatible with Tiled's JSON plugin

        classmethod TileLayer.from_dict(dct, *args, **kwargs)
            Import from a dict compatible with Tiled's JSON plugin
```

```
class tmxlib.layer.ObjectLayer
    NamedList methods

        ObjectLayer.__getitem__(index_or_name)
            Same as list's, except non-slice indices may be names.
```

`ObjectLayer.__setitem__(index_or_name, value)`
 Same as list's, but non-slice indices may be names instead of ints.

`ObjectLayer.__contains__(item_or_name)`
`item_or_name` in `self`

NamedElementLists can be queried either by name or by item.

`ObjectLayer.count(value) → integer` – return number of occurrences of value

`ObjectLayer.append(value)`
`S.append(object)` – append object to the end of the sequence

`ObjectLayer.extend(values)`
`S.extend(iterable)` – extend sequence by appending elements from the iterable

`ObjectLayer.pop([index]) → item` – remove and return item at index (default last).
 Raise IndexError if list is empty or index is out of range.

`ObjectLayer.remove(value)`
`S.remove(value)` – remove first occurrence of value. Raise ValueError if the value is not present.

`ObjectLayer.reverse()`
`S.reverse()` – reverse *IN PLACE*

`ObjectLayer.insert(index_or_name, value)`
 Same as list.insert, except indices may be names instead of ints.

`ObjectLayer.insert_after(index_or_name, value)`
 Insert the new value after the position specified by `index_or_name`

For numerical indexes, the same as `insert(index + 1, value)`. Useful when indexing by strings.

`ObjectLayer.move(index_or_name, amount)`
 Move an item by the specified number of indexes

`amount` can be negative. For example, “move layer down” translates to `layers.move(idx, -1)`

The method will clamp out-of range amounts, so, for example, `lst.move(0, -1)` will do nothing.

`ObjectLayer.retrieved_value(item)`
 Called when an item is being retrieved from the list.

Return the object that will actually be retrieved.

This method must undo any modifications that `stored_value` does.

`ObjectLayer.stored_value(item)`

Layer methods

`ObjectLayer.to_dict()`
 Export to a dict compatible with Tiled's JSON plugin

`classmethod ObjectLayer.from_dict(dct, *args, **kwargs)`
 Import from a dict compatible with Tiled's JSON plugin

`class tmxlib.layer.ImageLayer`

Layer methods

```
ImageLayer.to_dict()  
    Export to a dict compatible with Tiled's JSON plugin  
classmethod ImageLayer.from_dict (dct, *args, **kwargs)  
    Import from a dict compatible with Tiled's JSON plugin
```

class tmxlib.layer.LayerList

NamedList methods

```
LayerList.__getitem__ (index_or_name)  
    Same as list's, except non-slice indices may be names.  
LayerList.__setitem__ (index_or_name, value)  
    Same as list's, but non-slice indices may be names instead of ints.  
LayerList.__contains__ (item_or_name)  
    item_or_name in self  
    NamedElementLists can be queried either by name or by item.  
LayerList.index (value) → integer – return first index of value.  
    Raises ValueError if the value is not present.  
LayerList.count (value) → integer – return number of occurrences of value  
LayerList.append (value)  
    S.append(object) – append object to the end of the sequence  
LayerList.extend (values)  
    S.extend(iterable) – extend sequence by appending elements from the iterable  
LayerList.pop ([index]) → item – remove and return item at index (default last).  
    Raise IndexError if list is empty or index is out of range.  
LayerList.remove (value)  
    S.remove(value) – remove first occurrence of value. Raise ValueError if the value is not present.  
LayerList.reverse ()  
    S.reverse() – reverse IN PLACE  
LayerList.insert (index_or_name, value)  
    Same as list.insert, except indices may be names instead of ints.  
LayerList.insert_after (index_or_name, value)  
    Insert the new value after the position specified by index_or_name  
    For numerical indexes, the same as insert(index + 1, value). Useful when indexing by strings.  
LayerList.move (index_or_name, amount)  
    Move an item by the specified number of indexes  
    amount can be negative. For example, “move layer down” translates to layers.move(idx, -1)  
    The method will clamp out-of range amounts, so, for example, lst.move(0, -1) will do nothing.  
LayerList.modification_context (*args, **kwds)  
    Context in which all modifications take place.  
    The default implementation nullifies the modifications if an exception is raised.
```

Note that the manager may nest, in which case the outermost one should be treated as an atomic operation.

`LayerList.retrieved_value(item)`

Called when an item is being retrieved from the list.

Return the object that will actually be retrieved.

This method must undo any modifications that stored_value does.

`LayerList.stored_value(layer)`

Prevent layers that aren't from this map.

`class tmxlib.tileset.TilesetList`

NamedList methods

`TilesetList.__getitem__(index_or_name)`

Same as list's, except non-slice indices may be names.

`TilesetList.__setitem__(index_or_name, value)`

Same as list's, but non-slice indices may be names instead of ints.

`TilesetList.__contains__(item_or_name)`

item_or_name in *self*

NamedElementLists can be queried either by name or by item.

`TilesetList.index(value) → integer – return first index of value.`

Raises ValueError if the value is not present.

`TilesetList.count(value) → integer – return number of occurrences of value`

`TilesetList.append(value)`

S.append(object) – append object to the end of the sequence

`TilesetList.extend(values)`

S.extend(iterable) – extend sequence by appending elements from the iterable

`TilesetList.pop([index]) → item – remove and return item at index (default last).`

Raise IndexError if list is empty or index is out of range.

`TilesetList.remove(value)`

S.remove(value) – remove first occurrence of value. Raise ValueError if the value is not present.

`TilesetList.reverse()`

S.reverse() – reverse IN PLACE

`TilesetList.insert(index_or_name, value)`

Same as list.insert, except indices may be names instead of ints.

`TilesetList.insert_after(index_or_name, value)`

Insert the new value after the position specified by index_or_name

For numerical indexes, the same as `insert(index + 1, value)`. Useful when indexing by strings.

`TilesetList.move(index_or_name, amount)`

Move an item by the specified number of indexes

amount can be negative. For example, “move layer down” translates to `layers.move(idx, -1)`

The method will clamp out-of range amounts, so, for example, `lst.move(0, -1)` will do nothing.

`TilesetList.retrieved_value(item)`

Called when an item is being retrieved from the list.

Return the object that will actually be retrieved.

This method must undo any modifications that `stored_value` does.

`TilesetList.stored_value(item)`

Called when an item is being inserted into the list.

Return the object that will actually be stored.

To prevent incompatible items, subclasses may raise an exception here.

This method must undo any modifications that `retrieved_value` does.

`class tmxlib.tileset.ImageTileset`

Load/save methods (see `tmxlib.fileio.ReadWriteBase`):

classmethod `ImageTileset.open(filename, shared=False)`

Load an object of this class from a file

Parameters

- **filename** – The file from which to load
- **shared** – Objects loaded from a single file with `shared=True` will be reused. Modifications to this shared object will, naturally, be visible from all variables that reference it. (External tilesets are loaded as `shared` by default.)

classmethod `ImageTileset.load(string)`

Load an object of this class from a string.

Parameters `string` – String containing the XML description of the object, as it would be read from a file.

`ImageTileset.save(filename)`

Save this object to a file

Parameters `filename` – Name of the file to save to.

`ImageTileset.dump(string)`

Save this object as a string

Returns String with the representation of the object, suitable for writing to a file.

`ImageTileset.to_dict(**kwargs)`

Export to a dict compatible with Tiled's JSON plugin

classmethod `ImageTileset.from_dict(dct, *args, **kwargs)`

Import from a dict compatible with Tiled's JSON plugin

Overridden methods (see `tmxlib.tileset.Tileset`):

`ImageTileset.tile_image(number)`

Return the image used by the given tile

GID calculation methods (see `tmxlib.tileset.Tileset`):

Note: `TilesetList` depends on the specific GID calculation algorithm provided by these methods to renumber a map's tiles when tilesets are moved around. Don't override these unless your subclass is not used with vanilla TilesetLists.

`ImageTileset.first_gid(map)`

Return the first gid used by this tileset in the given map

```
ImageTileset.end_gid(map)
    Return the first gid after this tileset in the given map

class tmxlib.mapobject.RectangleObject
    MapObject methods
        RectangleObject.to_dict()
        classmethod RectangleObject.from_dict(dct, *args, **kwargs)

class tmxlib.mapobject.EllipseObject
    MapObject methods
        EllipseObject.to_dict()
        classmethod EllipseObject.from_dict(dct, *args, **kwargs)

class tmxlib.draw.DrawImageCommand
    DrawCommand methods
        DrawImageCommand.draw(canvas)
```
